Abstract

Proportional symbol maps visualize numerical data associated with point locations by placing a scaled symbol—typically an opaque disk or square—at the corresponding point on a map. The area of each symbol is proportional to the numerical value associated with its location. Every visually meaningful proportional symbol map will contain at least some overlapping symbols. These need to be drawn in such a way that the user can still judge their relative sizes accurately.

Figure 3: Algorithmic Aspects of Proportional Symbol Maps

Physically realizable drawings

Figure 4: Physically realizable vs. stacking drawings vs. impossible

$$U_i^{vis} = \partial D_i \setminus \bigcup_{j>i} D_j$$

$$U_i^{cov} = \partial D_i \cap \bigcup_{j>i} D_j.$$

$$\lambda_{min}(D) = \min_{i \in [n]} |U_i^{vis}|$$

$$\lambda_{sum}(D) = \sum_{i=1}^n |U_i^{vis}|$$

Why this lab?

$$\phi : \{1, \dots, n\} \mapsto D$$

Maps and Glyphs

(a) centered nested disks

(b) arbitrary nested disks

(c) pie charts

(d) squares

Algorithms

The visibility score of a drawing

1. assign local utility to each glyph
2. utility of the drawing (global utility) is the minimum (or sum) of the local utilities for each glyph

Theorem: Given as finite set D of n glyphs, a local utility function $\Gamma(d, S) \in \mathbb{R}_{>0}$ for $d \in D$ and $S \subseteq D$, which is anti-monotonous in S and a global utility function λ as the minimum of the local utilities, then the GreedyStacking algorithm computes an optimal stacking order.

Greedy Stackings

Theorem: Given as finite set D of n glyphs, a local utility function $\Gamma(d, S) \in \mathbb{R}_{>0}$ for $d \in D$ and $S \subseteq D$, which is anti-monotonous in S and a global utility function λ as the minimum of the local utilities, then the GreedyStacking algorithm computes an optimal stacking order.

GreedyStacking(D)

```
while( $D \neq \emptyset$ ) {  
     $x = \operatorname{argmin}_{d \in D} \Gamma(d, D \setminus d)$   
    print  $x$   
     $D := D \setminus x$   
}
```

Figure 6: Minimum or sum of visible boundary

Figure 7: Attachment point for the Hawaiian Glyph

Figure 8: Covered Piechart with relevant segment marked in red

Theorem: It is NP-hard to decide whether for a given set of pie glyphs there is a physically realizable drawing with global utility greater or equal to some value k .

Corollary: If we find an algorithm that computes an optimal physically realizable drawing in polynomial time, then $P = NP$.

Proof: Reduction from *planar-3SAT*.

Squares

Figure 9: mosaic square and associated pie glyph

Experimental results

Experimental Setup

- We use the John Hopkins University Covid-19 data
- recovered are coloured green, deceased are coloured black and the infected are coloured red
- logarithmic scaling dependent on two parameters:

$$r = M * \log \left(\frac{c_i S}{c_{max}} + 1 \right)$$

M is the maximum size of a glyph, S is a scaling factor and c_{max} is the maximum number of cases

Conclusion and Outlook

Summary

- Four glyphs were shown, with two new approaches.
- NP-hardness of new approaches was outlined.
- Heuristics and greedy approach usually are good choices.
- Square/pie approach can be interpreted as discrete version of the relative visibility.
- All of this was verified on the most recent COVID-19 data,
- and experimentally demonstrated.
