Proportional symbol maps visualize numerical data associated with point locations by placing a scaled symbol —typically an opaque disk or square—at the corresponding point on a map. The area of each symbol is proportional to the numerical value associated with its location. Every visually meaningful proportional symbol map will contain at least some overlapping symbols. These need to be drawn in such a way that the user can still judge their relative sizes accurately.

## Maps and Glyphs

# Why this lab? (1/2)

$$\phi: \{1,...,n\} \mapsto D$$

# Why this lab? (2/2)

$$\phi: \{1, ..., n\} \mapsto D$$

$$\phi: \{(1_1,1_2,1_3,...),...,(n_1,n_2,n_3,...)\} \mapsto D_i$$

# **Algorithms**

#### **Prior**

David's part. See Philip's list and or discussion.

#### Generalized

See Philip's list and or discussion.

### Our approach

See Philip's list and or discussion.

#### **Nested circles**

#### Nested circles with additional degrees of freedom

#### **Pies**

### **Squares**

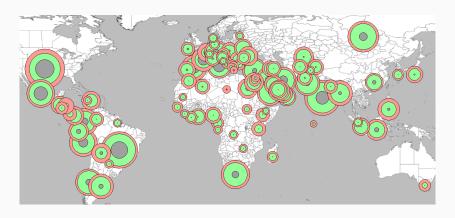

# Experimental results

#### **Experimental Setup**

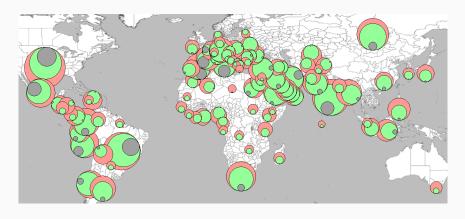

- We use the John Hopkins University Covid-19 data
- recovered are coloured green, deceased are coloured black and the infected are coloured red
- logarithmic scaling dependent on two parameters:

$$r = M * \log \left( \frac{c_i S}{c_{max}} + 1 \right)$$

M is the maximum size of a glyph, S is a scaling factor and  $c_{max}$  is the maximum number of cases

**Exploration in App** 

#### **Exploration of the data**

[Switch to app and play!]

**Conclusion and Outlook** 

#### **Summary**

- Four glyphs were shown, with two new approaches.
- NP-hardness of new approaches was outlined.
- Heuristics and greedy approach usually are good choices.
- Square/pie approach can be interpreted as discrete version of the relative visibility.
- All of this was verified on the most recent COVID-19 data,
- and experimentally demonstrated.
